Re: Mrs. Louise Stoten, DOB 08/04/1969

Dear Roger,

Thank you for your support with Louise. She is a 56-year-old woman with widely metastatic ER+ breast carcinoma, initially treated with paclitaxel and bevacizumab at our clinic with good response, later progressing on endocrine therapy.

She has now developed **volatile inflammatory markers and hypoxic pneumonia**, with a recent **CRP spike following prolonged neutropenia**. Despite 7 days of ertapenem (after an initial partial response) and no prior benefit from moxifloxacin, she remains fatigued and hypoxic. I am highly concerned about **Pneumocystis jirovecii pneumonia**, though **lymphangitic carcinomatosis progression** remains possible. CXR is unchanged; her most recent CT (on arrival to the UK) confirmed further disease progression.

Given her complex background and rapid decline, I would value your urgent input regarding further respiratory evaluation, antimicrobial strategy, and assessment for ongoing systemic options (including eribulin, as previously considered).

With appreciation,

Yours sincerely,

Dr James Laporta
